Requirements Analysis

- Requirements analysis
  - specifies software’s operational characteristics
  - indicates software's interface with other system elements
  - establishes constraints that software must meet

- Requirements analysis allows the software engineer (called an analyst or modeler) to:
  - elaborate on basic requirements established during earlier requirement engineering tasks
  - build models that depict user scenarios, functional activities, problem classes and their relationships, system and class behavior, and the flow of data as it is transformed.
A Bridge

- System description
- Analysis model
- Design model
Domain Analysis

- As part of Requirement Analysis, this is done for software reuse:
  - Can I use these designs for similar applications in the same domain?
  - Define the domain to be investigated.
  - Collect a representative sample of applications in the domain.
  - Analyze each application in the sample.
  - Develop an analysis model for the objects.
Elements of Requirements Analysis: Different Viewpoints

- **Scenario-based models**: e.g., use cases, user stories
- **Class models**: e.g., class diagrams, collaboration diagrams
- **Behavioral models**: e.g., state diagrams, sequence diagrams
- **Flow Models**: e.g., DFDs, data models

Scenario-Based Modeling

“[Use-cases] are simply an aid to defining what exists outside the system (actors) and what should be performed by the system (use-cases).” Ivar Jacobson

(1) What should we write about?
(2) How much should we write about it?
(3) How detailed should we make our description?
(4) How should we organize the description?
What to Write About?

- Inception and elicitation—provide you with the information you’ll need to begin writing use cases.
- Requirements gathering meetings and other requirements engineering mechanisms are used.
- To begin developing a set of use cases, list the functions or activities performed by a specific actor.
How Much to Write About?

- As further conversations with the stakeholders progress, the requirements gathering team develops use cases for each of the functions noted.

- In general, use cases are written first in an informal narrative fashion.

- If more formality is required, the same use case is rewritten using a structured format similar to the one proposed (template page 160).
<table>
<thead>
<tr>
<th>Use case:</th>
<th>Issue bike</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actors:</td>
<td>Receptionist</td>
</tr>
<tr>
<td>Goal:</td>
<td>To hire out a bike</td>
</tr>
</tbody>
</table>

Description:
When a customer comes into the shop they choose a bike to hire. The Receptionist looks up the bike on the system and tells the customer how much it will cost to hire for a specified period. The customer pays, is issued with a receipt, then leaves with the bike.
Use case: Issue bike
Actors: Receptionist
Goal: To hire out a bike

Overview:
When a customer comes into the shop they choose a bike to hire. The receptionist looks up the bike on the system and tells the customer how much it will cost to hire the bike for a specified period. The customer pays, is issued with a receipt, then leaves with the bike.

Typical course of events

<table>
<thead>
<tr>
<th>Actor action</th>
<th>System response</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. The customer chooses a bike</td>
<td></td>
</tr>
<tr>
<td>2. The Receptionist keys in the bike number</td>
<td>3. Displays the bike details</td>
</tr>
<tr>
<td>4. Customer specifies length of hire</td>
<td></td>
</tr>
<tr>
<td>5. Receptionist keys this in</td>
<td>6. Displays total hire cost</td>
</tr>
<tr>
<td>7. Customer agrees the price</td>
<td></td>
</tr>
<tr>
<td>10. Customer pays the total cost</td>
<td></td>
</tr>
<tr>
<td>11. Receptionist records amount paid</td>
<td>12. Prints a receipt</td>
</tr>
</tbody>
</table>

Alternative courses
Steps 8 and 9. The customer details are already in the system so the Receptionist needs only to key in an identifier and the system will display the customer details.
Steps 7 – 12. The customer may not be happy with the price and may terminate the transaction.
Developing a Use-Case

- What are the main tasks or functions that are performed by the actor?
- What system information will the actor acquire, produce or change?
- Will the actor have to inform the system about changes in the external environment?
- What information does the actor desire from the system?
- Does the actor wish to be informed about unexpected changes?
Preliminary Use-Case Diagrams for SafeHome

- Access camera surveillance via the Internet
- Configure SafeHome system parameters
- Set alarm

Homeowner

SafeHome

Cameras
Activity Diagram of First Use Case using UML

Supplements the use case by providing a graphical representation of the flow of interaction within a specific scenario.
Class-Based Modeling

Class-based modeling represents:
- **objects** that the system will manipulate
- **operations** (also called methods or services) that will be applied to the objects to effect the manipulation
- **relationships** (some hierarchical) between the objects
- **collaborations** that occur between the classes that are defined.

The elements of a class-based model include classes and objects, attributes, operations, CRC models, collaboration diagrams and packages.
Identifying Analysis Classes

- Examining the usage scenarios developed as part of the requirements model and perform a "grammatical parse" [Abb83]
  - Classes are determined by underlining each noun or noun phrase and entering it into a simple table.
  - Synonyms should be noted.
  - If the class (noun) is required to implement a solution, then it is part of the solution space; otherwise, if a class is necessary only to describe a solution, it is part of the problem space.

- But what should we look for once all of the nouns have been isolated?
Manifestations of Analysis Classes

- Analysis classes manifest themselves in one of the following ways:
  - External entities (e.g., other systems, devices, people) that produce or consume information
  - Things (e.g., reports, displays, letters, signals) that are part of the information domain for the problem
  - Occurrences or events (e.g., a property transfer or the completion of a series of robot movements) that occur within the context of system operation
  - Roles (e.g., manager, engineer, salesperson) played by people who interact with the system
  - Organizational units (e.g., division, group, team) that are relevant to an application
  - Places (e.g., manufacturing floor or loading dock) that establish the context of the problem and the overall function
  - Structures (e.g., sensors, four-wheeled vehicles, or computers) that define a class of objects or related classes of objects
Potential Classes (to be included in Analysis Model)

- Retained information. The potential class will be useful during analysis only if information about it must be remembered so that the system can function.
- Needed services. The potential class must have a set of identifiable operations that can change the value of its attributes in some way.
- Multiple attributes. During requirement analysis, the focus should be on "major" information; a class with a single attribute may, in fact, be useful during design, but is probably better represented as an attribute of another class during the analysis activity.
- Common attributes. A set of attributes can be defined for the potential class and these attributes apply to all instances of the class.
- Common operations. A set of operations can be defined for the potential class and these operations apply to all instances of the class.
- Essential requirements. External entities that appear in the problem space and produce or consume information essential to the operation of any solution for the system will almost always be defined as classes in the requirements model.
Defining Attributes

- **Attributes** describe a class that has been selected for inclusion in the analysis model.
- build two different classes for professional baseball players
  - **For Playing Statistics software:** name, position, batting average, fielding percentage, years played, and games played might be relevant
  - **For Pension Fund software:** average salary, credit toward full vesting, pension plan options chosen, mailing address, and the like.
Defining Operations

- Do a grammatical parse of a processing narrative and look at the verbs

- Operations can be divided into four broad categories:
  - (1) operations that manipulate data in some way (e.g., adding, deleting, reformatting, selecting)
  - (2) operations that perform a computation
  - (3) operations that inquire about the state of an object, and
  - (4) operations that monitor an object for the occurrence of a controlling event.
CRC Models

Class-responsibility-collaborator (CRC) modeling [Wir90] provides a simple means for identifying and organizing the classes that are relevant to system or product requirements. Ambler [Amb95] describes CRC modeling in the following way:

A CRC model is really a collection of standard index cards that represent classes. The cards are divided into three sections. Along the top of the card you write the name of the class. In the body of the card you list the class responsibilities on the left and the collaborators on the right.
## CRC Modeling

### Class: FloorPlan

<table>
<thead>
<tr>
<th>Responsibility</th>
<th>Collaborator</th>
</tr>
</thead>
<tbody>
<tr>
<td>defines floor plan name/type</td>
<td></td>
</tr>
<tr>
<td>manages floor plan positioning</td>
<td></td>
</tr>
<tr>
<td>scales floor plan for display</td>
<td></td>
</tr>
<tr>
<td>scales floor plan for display</td>
<td></td>
</tr>
<tr>
<td>incorporates walls, doors and windows</td>
<td>Wall</td>
</tr>
<tr>
<td>shows position of video cameras</td>
<td>Camera</td>
</tr>
</tbody>
</table>
Class Types in CRC

- **Entity classes**, also called *model* or *business classes*, are extracted directly from the statement of the problem (e.g., FloorPlan and Sensor).

- **Boundary classes** are used to create the interface (e.g., interactive screen or printed reports) that the user sees and interacts with as the software is used.

- **Controller classes** manage a “unit of work” [UML03] from start to finish. That is, controller classes can be designed to manage:
  - the creation or update of entity objects;
  - the instantiation of boundary objects as they obtain information from entity objects;
  - complex communication between sets of objects;
  - validation of data communicated between objects or between the user and the application.
Responsibilities

- System intelligence should be distributed across classes to best address the needs of the problem.
- Each responsibility should be stated as generally as possible.
- Information and the behavior related to it should reside within the same class.
- Information about one thing should be localized with a single class, not distributed across multiple classes.
- Responsibilities should be shared among related classes, when appropriate.
Collaborations

- Classes fulfill their responsibilities in one of two ways:
  - A class can use its own operations to manipulate its own attributes, thereby fulfilling a particular responsibility, or
  - a class can collaborate with other classes.

- Collaborations identify relationships between classes

- Collaborations are identified by determining whether a class can fulfill each responsibility itself

- three different generic relationships between classes [WIR90]:
  - the \textit{is-part-of} relationship
  - the \textit{has-knowledge-of} relationship
  - the \textit{depends-upon} relationship
Composite Aggregate Class (is-part-of Example in UML)
Associations and Dependencies

- Two analysis classes are often related to one another in some fashion
  - In UML these relationships are called *associations*
  - Associations can be refined by indicating *multiplicity* (the term *cardinality* is used in data modeling)
- In many instances, a client-server relationship exists between two analysis classes.
  - In such cases, a client-class depends on the server-class in some way and a *dependency relationship* is established
Multiplicity

Various elements of the analysis model (e.g., use-cases, analysis classes) are categorized in a manner that packages them as a grouping.

The plus sign preceding the analysis class name in each package indicates that the classes have public visibility and are therefore accessible from other packages.

Other symbols can precede an element within a package. A minus sign indicates that an element is hidden from all other packages and a # symbol indicates that an element is accessible only to packages contained within a given package.

See the example on video game in the next slide.
Analysis Packages

Reviewing the CRC Model

- All participants in the review (of the CRC model) are given a subset of the CRC model index cards.
  - Cards that collaborate should be separated (i.e., no reviewer should have two cards that collaborate).
- All use-case scenarios (and corresponding use-case diagrams) should be organized into categories.
- The review leader reads the use-case deliberately.
  - As the review leader comes to a named object, she passes a token to the person holding the corresponding class index card.
- When the token is passed, the holder of the class card is asked to describe the responsibilities noted on the card.
  - The group determines whether one (or more) of the responsibilities satisfies the use-case requirement.
- If the responsibilities and collaborations noted on the index cards cannot accommodate the use-case, modifications are made to the cards.
  - This may include the definition of new classes (and corresponding CRC index cards) or the specification of new or revised responsibilities or collaborations on existing cards.
Data Modeling

- examines data objects independently of processing
- focuses attention on the data domain
- creates a model at the customer’s level of abstraction
- indicates how data objects relate to one another
What is a Data Object?

- A representation of almost any composite information that must be understood by software.
  - *composite information*—something that has a number of different properties or attributes

- Can be an **external entity** (e.g., anything that produces or consumes information), a **thing** (e.g., a report or a display), an **occurrence** (e.g., a telephone call) or event (e.g., an alarm), a **role** (e.g., salesperson), an **organizational unit** (e.g., accounting department), a **place** (e.g., a warehouse), or a **structure** (e.g., a file).

- The description of the data object incorporates the data object and all of its attributes.

- A data object encapsulates data only—there is no reference within a data object to operations that act on the data.
Data Objects and Attributes

A data object contains a set of attributes that act as an aspect, quality, characteristic, or descriptor of the object.

object: automobile
attributes:
  make
  model
  body type
  price
  options code
What is a Relationship?

- Data objects are connected to one another in different ways.
  - A connection is established between person and car because the two objects are related.
    - A person owns a car
    - A person is insured to drive a car
  - The relationships owns and insured to drive define the relevant connections between person and car.
- Several instances of a relationship can exist
- Objects can be related in many different ways
